Abstract

Cryopreservation, the most popular way to preserve human sperm, led to a significant decline in sperm motility. Here, we tried to introduce a new method to store sperm without freezing. Different concentrations of genistein were added to liquid preserved sperm. We investigated the effects of supplementation on sperm total antioxidative capacity (T-AOC), glutathione (GSH), methane dicarboxylic aldehyde (MDA), acrosomal enzyme activity and fertilization ability of sperm. The effects of liquid storage and cryopreservation on sperm parameters were also compared. IVF medium supplemented with genistein (20µmol L⁻¹) maintained sperm motility for up to 11 days. The addition of genistein led to a decrease in reactive oxygen species (ROS) generation that demonstrated an effective improvement in sperm motility and decreased the MDA production and maintained the GSH content and enhanced the oxidative stress resistance ability of the sperm during liquid storage. The storage sperm were used for intracytoplasmic sperm injection (ICSI) into human oocytes and activated oocytes successfully. Sperm stored in liquid medium containing genistein was superior to sperm stored in liquid nitrogen in terms of antioxidant stress and fertilization ability. We confirmed that genistein could be used as an antioxidant for liquid storage of sperm. Sperm stored in IVF medium with genistein could avoid cryodamage, which may become an alternative option in assisted reproduction technology.

Keywords: Antioxidant, Assisted reproductive technology, ROS, Sperm motility, Sperm preservation.

Introduction

Cryopreservation of human sperm has been carried out in many fields, such as andrology laboratories and assisted reproduction centers. Human sperm cryopreservation shows a valuable therapeutic approach in management of male infertility [1]. However, there will lead to many adverse effects on sperm motility, viability and acrosome status when sperm are exposed to chemical and physical stresses during cryopreservation [2-6]. After cryopreservation, all these effects will reduce the fertilization ability of human sperm [7]. Alternative methods are required for the negative effects of sperm cryopreservation.

In animals, many methods of sperm preservation without freezing...
have been tried, such as preservation in sugars or salt and the evaporative drying [8-10]. In humans, sperm were attempted to be stored in a buffer containing egg yolk, Tris and TES without freezing up to 96 h [11-13]. However, sperm motility declined rapidly when sperm were stored in the buffer for 24 h [13]. It was reported that the frequency of structural changes increased when sperm chromosomes were evaluated after preservation [14,15]. Therefore, storage in this medium was considered mostly ineffective [16,17].

During sperm preservation, the occurrence of reactive oxygen species (ROS) would lead to oxidative stress [18]. The damage to sperm induced by ROS results in lipid peroxidation, which is caused by oxidative damage to sperm PUFAs (phospholipid-bound polyunsaturated fatty acids) [19,20]. There are various impacts of lipid peroxidation, such as decreased sperm motility, irreversible changes in sperm DNA and leakage of intracellular enzymes [21]. It also affects sperm penetration and prevents sperm-oocyte fusion [22]. Therefore, the generation of ROS needs to be reduced.

Genistein is an isoflavone that comes from soya or other legumes. Genistein inhibits protein tyrosine kinases and shows estrogen activity [23]. It modifies the capacitation and acrosome reaction process of mature sperm. Therefore, it affects a lot of functional parameters of mature sperm. In addition, the antioxidant capacity of genistein has been widely studied in vitro and also in vivo [24,25]. Furthermore, genistein can protect sperm DNA integrity through antioxidant activity [26].

In this study, we investigated the effects of the addition of genistein during liquid storage on sperm motility, T-AOC, GSH, MDA, acrosomal enzyme activity and fertilization ability of sperm. We compared the method of sperm storage in liquid with the traditional method of cryopreservation and found a new method to preserve sperm without freezing. Using this fundamental information, it would be possible to reduce the damage to sperm and improve the preservation process in ART.

Materials and Methods

Human sperm samples

The present study was approved by the institutional ethics committee review board of the Affiliated Yuhuangding Hospital of Qingdao University, Shandong, China. All men gave written informed consent prior to the start of the study. All semen samples were obtained from patients by masturbation who came for a semen analysis. These patients were abstinent from sexual activity for 2-7 days. Samples were collected into sterile containers and liquefied at room temperature. The samples were assessed for volume, pH, sperm concentration, percentage of sperm motility, percentage of normal morphology, and these analyses were according to the World Health Organization (WHO) guidelines [27].

Sperm preparation

Briefly, when the semen sample completed the liquefaction reaction, the entire semen was eased on the gradient medium consisting of 1.5 ml of 90% gradient medium and 1.5 ml of 45% gradient medium. Afterwards, the column was centrifuged at 300×g for 20 min at room temperature. After the centrifugal procedure, the pellet sperm was resuspended in 2 ml washing medium which was similar to medium used for storage. Then, the sperm was centrifuged again at 500×g for 10 min. At last, the supernatant part was separated and storage medium was added to the pellet to make a final concentration of 30-40×10^6 sperm/ml. It was then divided into a 1.5 ml tube with 0.5 ml sperm suspension /tube, sealed with mineral oil and stored for days at 24-26°C.

Sperm storage

Sperm were preserved in these four different media, including IVF (10136, Vitrolife, Sweden), Human Tubal Fluid medium (MR-070-D, Sigma, USA), FM (K-SIFM-100, Cook, Australia) and PBS (Sers, China). Genistein was purchased from Sigma Chemical Co (G-6649, USA) and dissolved in DMSO (D2650, Sigma, USA) to yield a 10 mmol L−1 stock solution. The stock solution was divided into aliquots and frozen at −20°C. The stock solution was diluted to the working solution with medium at the time of use. The cryopreservation method of sperm was as follows: the semen was centrifuged at 500×g for 10 min. Then, part of seminal plasma was removed and added equal volume cryoprotectant (ORIGIO, Denmark) and mixed well. Afterwards, the mixture was added to a 1.5 ml sperm cryopreservation tube and balanced at room temperature for 10 min and fumigated above liquid nitrogen for 30 min. Finally, it was put into liquid nitrogen storage.

Sperm motility analysis

Sperm motility was analyzed by a computer-assisted sperm analyzer (CASA) system (IVOSII, Hamilton, USA). Then, a 5-µL drop aliquot of sperm suspension was placed on a pre-warmed microscope slide and overlaid with a 22 mm² cover-slip. The slide was observed with a phase contrast microscope at 200× magnification. Ten fields of view were evaluated and counted a minimum of 1000 sperm per sample. Sperm with a VAP < 10 μm s⁻¹ were considered immotile.

Intracellular glutathione (GSH) measurement

Sperm samples were prepared as previously reported [28] with modifications. Briefly, 0.1 ml sperm suspension was placed in a centrifuge tube and centrifuged at 800×g for 15 min. After the supernatant was removed, the resulting sperm pellet was washed twice in Ca²⁺/Mg²⁺-free PBS by centrifugation at 400×g for 10 min. To release the intracellular content, the cells were broken by three cycles of rapid cooling in liquid nitrogen followed by thawing at 37°C. Then, the resulting cell suspension was centrifuged at 7000×g for 10 min to remove membrane fragments, and the supernatant was stored at −80°C until analyzed.

Intracellular GSH content was determined using a modified coupled optical test system [29]. In this system glutathione is oxidized by 5,5-dithiobis-(2-nitrobenzoic acid) (DTNB) and then reduced by glutathione reductase with NADPH as hydrogen donor. During the oxidation of glutathione by DTNB, 2-nitro-5-thiobenzoic acid is formed, which can be detected photometrically by a change of
Absorption at 412nm. The content of reduced glutathione (GSH) is calculated according to a standard curve.

**Total antioxidative capacity (T-AOC) measurement**

T-AOC was measured with commercial kits using enzymatic methods (Jiancheng Technology, Nanjing, China). The determination of T-AOC followed the operating manual. Sperm were centrifuged at 800×g for 10 min at room temperature to obtain supernatant. The supernatant recovered was stored at -80°C before use. Briefly, 1000μl Reagent 1, 100μl sample, 2000μl Reagent 2 and 500μl Reagent 3 were used for the reaction. The control tube contained Reagent1, Reagent 2 and Reagent 3 without the addition of sample. The sample tube and the control tube took a 30 minute water bath at 37°C. Then 100μl Reagent 4 was added to the tubes and 100μl sample was added to the control tube. The last absorbance was taken at the end of the incubation period (10 min after the mixing). The absorption value was measured at 520nm. This assay relies on the ability of antioxidants in the sample to reduce Fe^{3+}-TPTZ to Fe^{2+}-TPTZ. The absorption value of the sample tube was corrected by the absorption value of the control tube.

**Methane dicarboxylic aldehyde (MDA) measurement**

MDA was measured with commercial kits using enzymatic methods (Jiancheng Technology, Nanjing, China). The determination of MDA followed the operating manual. Sperm were centrifuged at 800×g for 10 min at room temperature to obtain supernatant. The supernatant recovered was stored at -80°C before use. Briefly, 100μl Reagent 1, 100μl sample, 3000μl Reagent 2 and 100μl Reagent 3 were used for the reaction. The control tube contained Reagent1, Reagent 2 and Reagent 3, and ethanol was added instead of the sample. The nozzle of the tubes was tightly covered with plastic film and a hole was punctured on top. The sample tube and control tube took a 40-minute water bath at 95°C and then centrifuged at 800×g for 10 min to obtain the supernatant. The absorption value of the supernatant was measured at 532nm. This determination depends on the reaction of MDA with TBA, which chemically binds to form another red substance. The red substance has a maximum absorption peak at 532nm. The absorption value of the sample tube was corrected by the absorption value of the control tube.

**Acrosomal enzyme activity measurement**

Acrosomal enzyme activity was measured with the quantitative assay kit (Huakang Medicine, Shenzhen, China). A modified Kennedy method was used to detect the acrosomal enzyme activity of sperm and follow the operating manual. The culture medium containing 7.5×10⁶ sperm was centrifuged at 8000×g for 5 min to obtain the pellet at the bottom of the tube. After the supernatant was discarded, 100μl inhibitor was added to the tube and mixed well. 1000μl reaction buffer and 100μl stop buffer were added to the control tube, but only reaction buffer was added to the sample tube. The sample tube and the control tube took a 30-minute water bath at 37°C, then 100μl stop buffer was added to the sample tube. The tubes were centrifuged at 4000×g for 5 min to obtain supernatant. The absorption value of the supernatant was measured at 410nm. This assay relies on the reaction of arginine amidase with nitroaniline, which chemically binds to form another colored substance. The absorption value of the sample tube was corrected by the absorption value of the control tube. The value was calculated as follows: (sample OD-control OD) ×10⁶/(247.5×7.5).

**Intracytoplasmic sperm injection**

The MII-stage oocytes used for ICSI were collected from MI-stage oocytes discarded by ICSI patients, which cultured in IVF medium for 20-24h in vitro. Sperm with the fastest movement and normal morphology were selected for injection. After injection, oocytes were transferred to G1 medium (10128, Vitrolife, Sweden) and cultured at 37.0°C. The fertilization rate of oocytes was scored after microinjection for 17-20h. The oocytes with two well-developed pronuclei and extruded second polar body were considered activated. On day 3, a quality score was given for cultured embryos, and those with 7-9 uniformly sized cleavage balls and a fragmentation rate of less than 20% were considered high-quality embryos. Embryos were transferred to GII medium (10132, Vitrolife, Sweden) for further development on the afternoon of day 3. On day 5 and day 6, only blastocysts with dilated blastocyst cavity, clearly visible inner cell masses and compact trophoblast cells were considered as available blastocysts.

**Statistical Analysis**

There were at least three replicates for each treatment. Percentage data were arc sine transformed and analyzed with ANOVA when each measure contained more than two groups or with an independent t-test when each measure had only two groups; a Duncan multiple comparison test was used to locate differences. The software used was Statistics Package for Social Science (SPSS 11.5; SPSS Inc., Chicago, IL, USA). Data were expressed as mean ± S.E.M. and P<0.05 was considered significant.

**Results**

**Effect of seminal plasma on sperm motility**

Sperm motility declined rapidly when stored as an unwashed semen (Figure 1A) and on day 5, average sperm motility was less than 1%. When the ratio of seminal plasma was more than 50%, sperm motility decreased quickly compared with sperm without seminal plasma (p<0.05). Unwashed semen storage caused rapid deterioration of sperm. It was not suitable for sperm storage.

**Effect of different media on sperm motility**

The motility of sperm stored in HTF and PBS medium decreased rapidly on the first day compared to sperm stored in IVF and FM medium. On day 3, the motility of sperm stored in FM medium began to decrease quickly, about a 50% reduction. The motility of sperm preserved with IVF medium was maintained longer than that of sperm stored in FM medium (Fig.1B). The average motility of sperm stored in IVF and FM medium for 5 days was 44.3±7.0% and 21.7±5.9% (p<0.05) respectively, about two times. Sperm...
From day 5, the activity of sperm acrosomal enzyme was maintained by adding genistein, which was significantly higher than that of the non-additive group (Figure 3D, P<0.05). On day 9, the acrosomal enzyme activity of sperm in the two groups was 90.7±2.3µIU and 52.3±4.3µIU (p<0.05) respectively, about two times. The acrosomal enzyme activity decreased from 180.3±4.7µIU to 123.2±5.7µIU after sperm were stored in liquid nitrogen (Figure 4D, P<0.05). The results showed that adding genistein may be an optimal method to maintain the acrosomal enzyme activity of sperm.

Effect of genistein and cryopreservation on sperm fertilization ability

Sperm were stored in IVF medium with addition of genistein (20µM) for different days and then used for ICSI into human oocytes to assess their ability to participate in assisted fertilization and embryo development (Table 1). Fresh sperm were injected as controls. Fertilization rates of oocytes were similar except the group that sperm stored in IVF medium without addition of genistein on day 9 when the motility of sperm was very low. There was no difference in embryo cleavage rate between all the groups. High quality embryo and blastocyst formation of sperm without addition of genistein on day 9 was significantly lower than that of other groups. The results showed that the sperm fertilization ability of genistein added on day 5 was similar to that of fresh sperm. After the sperm were stored in liquid nitrogen, the fertilization ability was similar to that of the sperm without adding genistein on day 5. Overall, the results demonstrated that sperm preserved in IVF medium with genistein for several days were functional in assisted fertilization.

Discussion

In this study, we showed that preservation of human sperm in IVF medium with genistein could maintain sperm motility for several days. Compared with the traditional cryopreservation method, this method can maintain sperm motility and antioxidant stress ability in a short time. It may be an alternative method for sperm preservation.
Figure 2: Effects of different concentrations of genistein supplementation on the motile sperm percentages. Sperm were stored in IVF medium with different concentrations of genistein at 24-26°C for 11 days. Each data point represents the mean ± SEM.

Figure 3: Effects of genistein supplementation on GSH, T-AOC, MDA, acrosomal enzyme activity of sperm. (A) Measurement of relative GSH content. (B) Measurement of relative T-AOC content. (C) Measurement of relative MDA content. The data(A-C) of day 0 was set to one and the data of other days were compared with the data of day 0. (D) Measurement of acrosomal enzyme activity. Each graph bar represents the mean ± SEM. Different letters within an assessment significantly different at P <0.05.
At present, cryopreservation of sperm is the only way to store human sperm, but this common method leads to a significant decline in sperm motility [30]. Cryopreservation leads to sperm DNA damage and may also bring hidden effects such as changed styles of intracellular enzyme activities and disturbed plasma membranes undetectable by supravital staining [31,32]. It has been demonstrated that sperm DNA damage leads to reduced reproductive outcomes such as adverse effects on fertilization rate and preimplantation development. It also causes pregnancy loss and morbidity [33]. Hence, it is important to keep sperm DNA integrity for the right conveyance of chromatin materials to the next generation. For successful assisted reproduction, it is necessary to develop a better way to maintain sperm DNA than cryopreservation.

Sperm stored without washing may be the simplest method of preservation without freezing, but sperm motility lost rapidly on the first day. Seminal plasma may contain something detrimental to sperm [34]. Seminal plasma can potentially protect sperm from DNA damage for containing...
a lot of antioxidant enzymes, but it also reduces sperm viability significantly for containing bacteria and leukocytes. However, seminal plasma also contains nucleases, which are detrimental to sperm with damaged membrane because it can enter and digest sperm DNA [35,36].

In our study, sperm preserved in HTF and PBS media suffered rapid quality loss. After three days of storage, sperm motility decreased rapidly in most media except IVF medium. When the four different media were compared, IVF medium was the best one for sperm storage that could maintain sperm quality well. It was reported that sperm motility declined to below 10% within a few days of being stored in HTF [37]. A lot of research has been carried out on the origin of DNA damage [38]. Recently, it was proved that sperm motility could be maintained long enough to participate in fertilization in vivo due to the presence of pro-survival factors. These pro-survival factors can prevent sperm from entering an apoptotic state [39]. These pro-survival factors, which may be present in IVF media rather than other media, can prevent sperm from entering the apoptotic pathway, or at least slow it down. Consequently, if the simple medium doesn’t contain pro-survival factors, it may facilitate sperm entry into the apoptotic pathway.

Reactive oxygen species directly caused sperm DNA damage [40]. The results showed that ROS damaged sperm nucleus and mitochondria, which were compatible with keeping sperm motility and fertilization ability [41]. The metabolic processes of sperm and exogenous chemicals produced ROS, which damaged sperm biological system. During cryopreservation, it has been proven that lipid peroxidation of sperm membrane increased probably because of ROS release [42]. Sperm were particularly vulnerable to ROS-induced damage because they contained large amounts of PUFA content. Thus, it was necessary to add antioxidants to reduce the effect of ROS on sperm [43].

Changes in redox balance between defense mechanisms and ROS generation were associated with sperm capacitation process [44]. Sperm motility and capacitation were related to protein phosphorylation. The inhibition of tyrosine kinase caused changes of sperm motility parameters [45]. Genistein is an inhibitor of tyrosine kinase that affects sperm motility in a dose-dependent manner. Low concentrations of genistein did not interfere with sperm motility in mice and human, but high doses had a negative effect on sperm motility, and then showed that sperm motility decreases with the addition of 400µmol/L genistein [45-47]. Here, we showed that sperm motility had a slight increase when 20µmol/L genistein was added to the liquid storage medium. The addition of genistein reduced the ROS generated during the liquid storage of sperm and these data indicated that genistein used at this concentration (20µmol/L) could offer antioxidant properties to sperm. We speculated that it was associated with the inhibition of tyrosine kinase and the process of capacitation [45].

In previous experiments, reduced glutathione was added to the medium to increase the percentage of viable sperm. During liquid storage, the increased oxidative stress was associated with the negative effects of ROS. The decrease of GRD activity and SOD activity led to the decrease of GSH content and the increase of superoxide anion formation. GSH oxidation also increased because of hydrogen peroxide. Increased ROS production and decreased intracellular GSH during fluid storage lead to decreased sperm motility. The addition of exogenous genistein during liquid storage would prevent ROS-induced damage and maintain sperm function. The results showed that low-dose genistein treatment could increase the serum testosterone level in mice and regulate expression of spermatogenesis related genes. Expressions of ESR2, CYP19A1, SOX9 and BRD7 in mouse testis increased after genistein treatment [48]. Estrogen receptors (ER2) mediated the effects of estrogen [49]. CYP19A1 genes played an important role in estrogen biosynthesis [50,51]. SOX9 was an indispensable regulator of germ cell survival and proliferation [52]. Genistein interacted with estrogen receptors and had important estrogen effects [53-55]. Hence, we speculated that genistein may play its role on sperm by regulating the expression of certain genes.

The method of storing sperm in liquid can be applied to the following types: Firstly, sperm with poor freezing resistance have normal motility before freezing, but the sperm quality of the patients decreases significantly after cryopreservation. There are pathological changes in the structure and function of sperm in some or many aspects. These congenital defects could make sperm vulnerable to freezing damage, resulting in poor freezing performance. Secondly, low quality sperm refers to a group of pathological semen specimens with abnormal semen routine parameters or low sperm basic functions, such as rare, weak and abnormal sperm. Low quality sperm have worse anti-freeze performance and changes in sperm function may have a greater impact. Thirdly, patients who have difficulty in masturbation do not need long-term sperm storage, and liquid storage may be a more appropriate method.

In summary, we have shown that the isoflavone genistein has antioxidant properties when added to the liquid storage medium of sperm. Genistein caused a decrease in ROS production and an increase in sperm motility. This short-term storage may be the best way to store human sperm without freezing. This approach could provide high-quality preserved sperm for subsequent assisted fertilization and may become a fundamental method for ART.
